

# Solution Review: Check Sum

This lesson provides the solution to the check sum exercise.

## WE'LL COVER THE FOLLOWING ^

- Solution
- Explanation

## Solution #

```
def check_sum(num_list, num):  
    for first_num in range(len(num_list)):  
        for second_num in range(first_num + 1, len(num_list)):  
            if num_list[first_num] + num_list[second_num] == num:  
                return True  
    return False  
  
num_list = [10, -14, 26, 5, -3, 13, -5]  
print (check_sum(num_list, -8))
```

## Explanation #

We used a nested `for` loop to obtain all the possible pairs in the list. By using `range()`, we make sure that the inner loop always starts one index ahead of the outer loop and this removes the possibility of a comparison being repeated.

---

Now that we are done with Python refresher, let's move on to arrays in Python.
