

# Firebase Hosting

Let's take a look at how Firebase can host our web application.

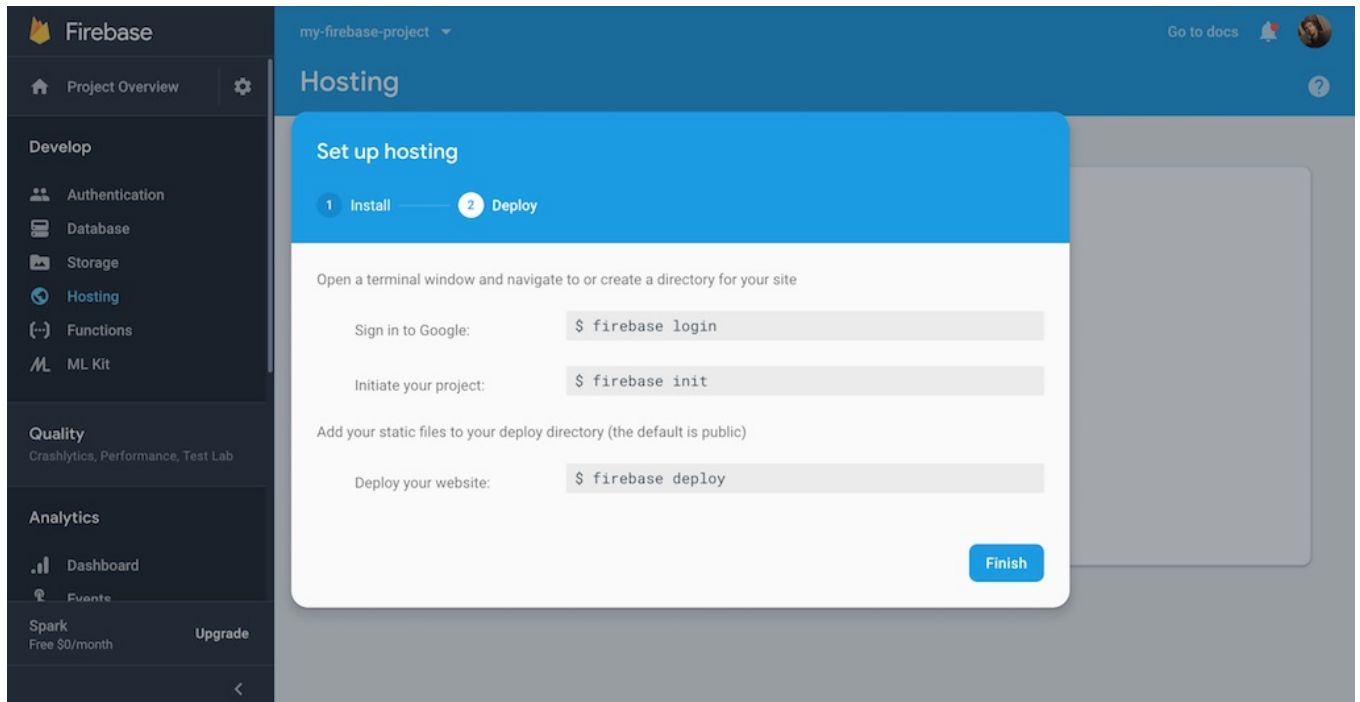

We can use Firebase to host our project on top of Google's infrastructure. Navigate to the **Hosting** option to get started on deployment.

First, we need to install the necessary node packages on the command line.

Then we can login with a Google account, initialize a Firebase application, and finally deploy it.

It's worth mentioning that Firebase Hosting comes with all essential features (e.g. analytics, domain support) that other hosting providers would offer as well.

---

Now that we know how to setup Firebase, we are ready to create and deploy a React application on the platform.
