- Examples

In this lesson, we will look at some examples of variadic templates.

WE'LL COVER THE FOLLOWING ^ Example 1 Explanation Example 2 Explanation

Example 1

```
// templateVariadicTemplates.cpp
#include <iostream>
template <typename... Args>
int printSize(Args... args){
  return sizeof ...(args);
template<int ...>
struct Mult;
template<>
struct Mult<>{
  static const int value= 1;
};
template<int i, int ... tail>
struct Mult<i, tail ...>{
  static const int value= i * Mult<tail ...>::value;
};
int main(){
  std::cout << std::endl;</pre>
  std::cout << "printSize(): " << printSize() << std::endl;</pre>
  std::cout << "printSize(template,2011,true): " << printSize("template",2011,true) << std::e</pre>
  std::cout << "printSize(1, 2.5, 4, 5, 10): " << printSize(1, 2.5, 4, 5, 10) << std::endl;
  std::cout << std::endl:</pre>
```

```
std::cout << "Mult<10>::value: " << Mult<10>::value << std::endl;
std::cout << "Mult<10,10,10>::value: " << Mult<10,10,10>::value << std::endl;
std::cout << "Mult<1,2,3,4,5>::value: " << Mult<1,2,3,4,5>::value << std::endl;
std::cout << std::endl;
}</pre>
```

[]

Explanation

- In the above example, we used a printSize function, which prints the number of elements (of any type) passed as arguments. It detects the number of elements on compile-time using the sizeof operator. In the case of an empty argument list, the function returns 0.
- There is a struct defined as Mult, which takes arguments of integer type and return their product. If no argument is passed, it returns 1, which is the neutral element for multiplication.
- The result is stored in the value, in the fully specialized template in lines 13 to 16. The partial specialization in lines 18 21 starts the recursion, which ends with the aforementioned fully specialization for 0.
- The primary template in line 10 is never used and must never be defined.

The three dots ... (ellipse) is used before Args if parameters should be packed and after Args if they should be unpacked.

To better visualize the template instantiation for the above-mentioned example click here.

Example 2

```
T createT(Args&& ... args){
  return T(std::forward<Args>(args) ...);
}
struct MyStruct{
  MyStruct(int&, double&, double&&){}
  friend std::ostream& operator<< (std::ostream& out, const MyStruct&){</pre>
      out << "MyStruct" << std::endl;</pre>
      return out;
  }
};
int main(){
  std::cout << std::endl;</pre>
  double myDouble= createT<double>();
  std::cout << "myDouble: " << myDouble << std::endl;</pre>
  int myInt= createT<int>(1);
  std::cout << "myInt: " << myInt << std::endl;</pre>
  std::string myString= createT<std::string>("My String");
  std::cout << "myString: " << myString << std::endl;</pre>
  MyStruct myStruct= createT<MyStruct>(myInt, myDouble, 3.14);
  std::cout << "myStruct: " << myStruct << std::endl;</pre>
  std::cout << std::endl;</pre>
```

[]

Explanation

- In the above example, we have created a createT function which invokes
 the constructor T with the arguments args. If no value is passed, it
 invokes the default constructor. The factory function createT can invoke
 each constructor.
- Due to perfect forwarding, each value can be used such as an lvalue or an rvalue. Due to parameter packs, each number of arguments can be used.
 In the case of MyStruct, a constructor requiring three arguments is used.
- The pattern of the function template createT is the same as the perfect
 factory functions, such as std::make_unique, std::make_shared,
 std::make_pair, or std::make_tuple.

packed and after Args if they should be unpacked.

In the next lesson, we will take a look at template arguments.
