Preview: Transfer Functions

Preview of transfer functions.

WE'LL COVER THE FOLLOWING ^

- Introduction
 - Series
 - Parallel
 - Operations

Introduction

The transfer function is a convenient representation of a linear time-invariant dynamical system. Mathematically, the transfer function is a function of complex variables.

A **transfer function** is the ratio of the output of a system to the input of a system. If we have an input function of X(s), and an output function Y(s), we define the transfer function H(s) to be:

$$H(s) = rac{Y(s)}{X(s)}$$
 $X(s) \longrightarrow Y(s)$

An example of a transfer function could be:

$$H(s) = rac{2s^3 + s^2 + 1}{2s^4 + 2s^2 + 3s}$$

where the output is:

$$2s^3 + s^2 + 1$$

and the input is:

$$2s^4 + 2s^2 + 3s$$

The behavior of **a system** is identified by its transfer function. We can get the output by simply multiplying the transfer function with the input function:

$$Y(s) = H(s)X(s)$$

Transfer functions can either be in series or parallel.

Series

If there is more than one system in the series, we **multiply** their individual transfer functions to get the **transfer function of the entire system**.

Suppose we have a system of three transfer functions in series:

The system transfer function will be:

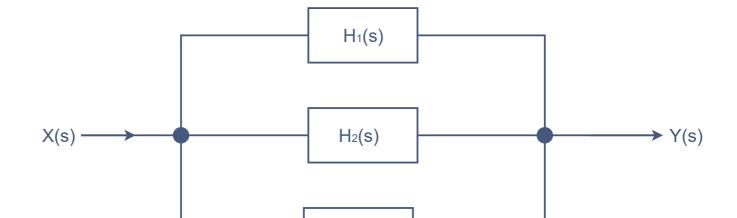

$$H(s) = H_1(s) imes H_2(s) imes H_3(s)$$

and the output will be:

$$Y(s) = H(s)X(s)$$

Parallel

If there is more than one system in the series, we **add** their individual transfer functions to get the **transfer function of the entire system**.

H₃(s)

The system transfer function will be:

$$H(s) = H_1(s) + H_2(s) + H_3(s)$$

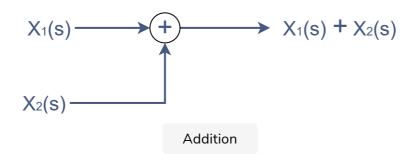

and the output will be:

$$Y(s) = H(s)X(s)$$

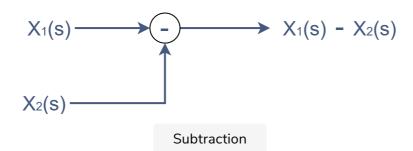

Operations

Arithmetic operations can also be performed on the inputs. Some useful examples of this are:

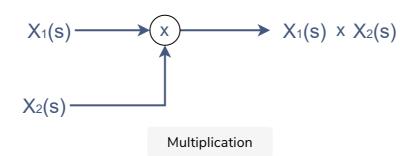

1. Addition

2. Subtraction

3. Multiplication

| In the next lesson, you will solve tasks related to transfer functions. | |
