Reduce

We often need to reduce a numeric range. That is where std::reduce comes in handy.

WE'LL COVER THE FOLLOWING ^

- reduce:
- transform_reduce:

The six new algorithms that are typically used for parallel execution are also known under the name prefix sum. If the given binary callables are not associative and commutative, the behavior of the algorithms is undefined.

reduce:

reduces the elements of the range. init is the start value.

• Behaves the same as std::accumulate but the range may be rearranged.

```
ValType reduce(InpIt first, InpIt last)
ValType reduce(ExePol pol, InpIt first, InpIt last)

T reduce(InpIt first, InpIt last, T init)
T reduce(ExePol pol, InpIt first, InpIt last, T init)

T reduce(InpIt first, InpIt last, T init, BiFun fun)
T reduce(ExePol pol, InpIt first, InpIt last, T init, BiFun fun)
```

transform_reduce:

transforms and reduces the elements of one or two ranges. init is the start value.

- Behaves similarly to std::inner_product but the range may be rearranged.
- If applied to two ranges
 - o if not provided, multiplication is used for transforming the ranges

into one range and addition is used to reduce the intermediate range into the result

- if provided, fun1 is used for the transforming step and fun2 is used for the reducing step
- If applied to a single range
 - fun2 is used for transforming the given range

```
T transform_reduce(InpIt first, InpIt last, InpIt first2, T init)
T transform_reduce(InpIt first, InpIt last, InpIt first2, T init, BiFun fun1, BiFun fun2)

T transform_reduce(FwdIt first, FwdIt last, FwdIt first2, T init)
T transform_reduce(ExePol pol, FwdIt first, FwdIt last, FwdIt first2, T init, BiFun fun1, BiFun fun1, BiFun fun2)
T transform_reduce(InpIt first, InpIt last, T init, BiFun fun1, UnFun fun2)
T transform_reduce(ExePol pol, FwdIt first, FwdIt last, T init, BiFun fun1, UnFun fun2)
```

i MapReduce in C++17

The Haskell function map is called std::transform in C++. When you substitute transform with map in the name std::transform_reduce, you will get std::map_reduce. MapReduce is the well-known parallel framework that first maps each value to a new value, then reduces in the second phase all values to the result.

The algorithm is directly applicable in C++17. In the following example, in the map phase, each word is mapped to its length, and the lengths of all words are then reduced to their sum during the reduce phase. The result is the sum of the length of all words.
