## - Exercise

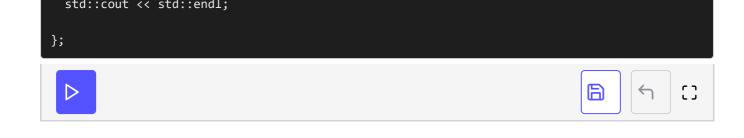

In this exercise, you will make a variadic template from the perfect factory method.

```
we'll cover the following ^
• Task
```

## Task #

Use the perfect factory method in the code below to make a variadic template and use it with different types.

```
#include <iostream>
#include <string>
#include <utility>
template <typename T, typename T1>
T create(T1&& t1){
  return T(std::forward<T1>(t1));
}
int main(){
  std::cout << std::endl;</pre>
  // Lvalues
  int five=5;
  int myFive= create<int>(five);
  std::cout << "myFive: " << myFive << std::endl;</pre>
  std::string str{"Lvalue"};
  std::string str2= create<std::string>(str);
  std::cout << "str2: " << str2 << std::endl;</pre>
  // Rvalues
  int myFive2= create<int>(5);
  std::cout << "myFive2: " << myFive2 << std::endl;</pre>
  std::string str3= create<std::string>(std::string("Rvalue"));
  std::cout << "str3: " << str3 << std::endl;</pre>
  std::string str4= create<std::string>(std::move(str3));
  std::cout << "str4: " << str4 << std::endl;</pre>
```

The solution to the exercise can be found in the next lesson.
